Endicott Wellfield hearing

2

1 MS. MILLER: Hello, and welcome to tonight's
2 meeting. My name is Sue Miller and I'm in charge of
3 citizen participation and public affairs for the State
4 Department of Environmental Conservation in this region of
5 the state.

6 Tonight, we are here to discuss and hear about
7 the draft remedial investigation and feasibility study for
8 the Ranney well in Endicott wellfield in the Town of Union.
9 Now, the remedial investigation feasibility study is a set
10 of four long words that basically mean that the remedial
11 investigation looks at the site, determines what type of
12 contamination exists and, where it exists, to what extent.

13 The feasibility study goes into detail with
14 regard to various alternatives for remedial action at the
15 site and recommends one particular alternative that is
16 chosen as the best or most feasible for this site. That's
17 what you'll be hearing about tonight, the remedial
18 investigation feasibility study.

19 The purpose of tonight's meeting is really
20 twofold. First of all, for those of you that may not have
21 weeded through yet or had the opportunity to go through the
22 four volumes of the report, it's to describe the report to
23 you; and then secondly, to take the comments and questions
24 from the public on this report.

END 002

15663

Endicott Wellfield hearing

3

1 The public comment period on this report ends
2 August 21st. After closure of the public comment period,
3 DEC will finalize the report and forward it to the
4 Environmental Protection Agency. Once the Environmental
5 Protection Agency receives it, that's the federal agency,
6 they review the report and they issue what's called a
7 record of decision which makes a final decision on this
8 recommended alternative. That record of decision is
9 expected in September and will be put on file the same
10 place that this report was put on file and that will be
11 made available at the Johnson Library. In addition, the
12 report was also made available in this building, the
13 municipal building. Notices have appeared in the Press/Sun
14 Bulletin and it has aired on WENE.

15 We hope that everyone here this evening has had
16 a opportunity to sign in so that we know who is able to
17 attend tonight's meeting. If you know of others who
18 weren't able to attend but were interested in this report
19 or if you have further comments to make after hearing
20 tonight's presentation, we invite you to get written
21 comments to Bob Cozzy at the New York State Department of
22 Environmental Conservation, 50 Wolf Road, Albany, and you
23 have up until the close of the public comment period,
24 August 21st, to get any written comments in.

END 002

18663

Endicott Wellfield hearing

4

1 Tonight's agenda is basically going to consist
2 of presentations by two consultants involved in putting the
3 report together, followed by some comments on the health
4 assessment which is part of the report that one of the
5 consultants will address. And then we will take questions
6 and comments from the audience.

7 Let me introduce who we have here at the table
8 tonight. We have Dr. Gaffney from Broome County Health
9 Department. We thank you for coming tonight, Dr. Gaffney;
10 Frank Ricotta, who is with our department in the Albany
11 office; Bob Cozzy, who is with DEC Albany who is the
12 project engineer in this particular site; we have Mike
13 O'Hara with TAMS, a consulting firm, the lead consulting
14 firm involved in putting this study together; and we have
15 Ray Kampff with GZA consultants, who will be the first
16 person to speak this evening and he'll address the remedial
17 investigation which his firm put together.

18 MR. KAMPFF: Thank you. Before we get started.
19 The remedial investigation that we did, I thought I'd give
20 you a little bit of background on the Endicott wellfield
21 site and exactly why remedial investigation study was
22 necessary for this site.

23 The Endicott wellfield project area is shown by
24 this sheeted area right here. Down in the corner is the

END 002

1564

Endicott Wellfield hearing

5

1 Ranney Well. The study area includes the Ranney Well and a
2 portion of its catchment included underneath the En-Joie
3 Golf Course and a portion of the Endicott sewage treatment
4 plant. To the south of the site you have the Susquehanna
5 River and bisecting the site is Nanticoke Creek.

6 Ranney well is a major component of the
7 Village of Endicott municipal water system. It pumps an
8 average of 3,700 gallons a minute and that comprises
9 approximately 47 percent of the total water supply for the
10 Village of Endicott. In May of 1981, the USEPA, during
11 routine testing of the water, detected various volatile
12 organic chemicals in the water. Primary concern was vinyl
13 chloride that was found at 8.4 parts per billion. Since
14 that time, the results in '81 were confirmed by additional
15 testing and remedial activity was undertaken on several
16 fronts.

17 The New York State DEC Division of Water
18 completed some hydrogeologic investigations at the site.
19 The village of Endicott expanded the analytical testing
20 program in hopes to pin down the source of the
21 contamination. As a result of those earlier studies,
22 various remedial activity has been completed to date. Some
23 of the activity included closing down some of the most
24 contaminated laterals in the well, installing a purge well

END 002

1565

Endicott Wellfield hearing

6

1 in an upgrading position of the Ranney Well to intercept
2 the contaminated ground water before it got into the Ranney
3 well.

4 In large parts, the remedial activities have
5 been successful in reducing the level of contamination in
6 the Ranney well such that vinyl chloride, in most
7 occasions, is not detected. However, on occasions, some
8 vinyl chloride does get to the Ranney well and some other
9 volatile organics are found in the Ranney well. Therefore,
10 the DEC in March of 1986 retained TAMS Consultants and
11 Goldberg-Zoino Associates acted as a sub-consultant to TAMS
12 to complete our remedial investigations at this site. And
13 the purpose of this remedial investigation study was; one,
14 to assess the extent of the contamination found in the
15 Ranney well; and two, to try to determine the location of
16 the contaminant source.

17 Our work included field activities that extended
18 from May 1986 to January '87. And some of the work just
19 briefly included review of the existing data, including the
20 monitoring wells that were installed by the DEC, analytical
21 test results, reports on nearby contaminant sources.

22 We also prepared a work quality assurance plan
23 and a health and safety plan that we followed during the
24 field investigation phase of the work.

END 002

15555

Endicott Wellfield hearing

7

1 We did topographic maps of the Endicott
2 wellfield site; survey at the locations of the test bore
3 sampling points that we put in.

4 We completed surface geophysical studies with
5 seismograph type studies to better determine the nature of
6 the soils and contamination at the site before we got into
7 a drilling program to assist us in positioning our
8 monitoring wells and sampling locations.

9 We activated three test pits around an abandoned
10 tannery sewer which earlier was suspected as a potential
11 contaminant source.

12 Additional work included the drilling and
13 sampling of 18 test borings with an average depth of
14 approximately 100 feet deep and the subsequent installation
15 of 18 monitoring wells constructed of stainless steel
16 screens and risers to monitor the ground water elevations
17 and the quality of the ground water.

18 During this work, we collected samples and
19 screened them in the field with a portable gas
20 chromatograph to aid us in positioning the wells and also
21 to use as a health and safety measure.

22 Additional work included ground water level
23 monitoring, testing of the soil types to determine the
24 permeability and the ground water characteristics.

END 002

1567

Endicott Wellfield hearing

8

1 We completed five sampling rounds from the
2 various media, including ground water, surface water,
3 sediments, waste samples, outbreak samples throughout the
4 site.

5 We collected that data and analyzed the data.
6 Part of that analysis included the development of a
7 mathematic computer ground water to simulate and predict
8 ground water flows at the site.

9 And finally, we prepared and submitted a
10 remedial investigations report which is on file. I guess
11 everyone has an opportunity to look at.

12 This site investigation map is kind of crowded
13 by the topouls (sic). You do have a handout that shows it
14 a little bit better. The Ranney well is located down in
15 the corner. The purge well that was put in by the DEC is
16 this location. The wells shown in red are the wells that
17 we installed during this study. The remaining wells were
18 installed by the DEC and as you can see, wells were
19 installed both on the En-Joie Golf and over around the
20 Endicott sewage treatment plant.

21 The geology based on the borings that were
22 completed, you can see this in general terms. The geology
23 of the site includes glacially deposited soils that were
24 deposited glacially. The geophysical testing indicated

END 002

15668

Endicott Wellfield hearing

9

1 that bedrock occurs between 140 and 200 feet at the site.
2 One test boring, MW-2, that was taken to bedrock
3 encountered bedrock at 170 feet.

4 In general, the geology of the Ranney well, the
5 Ranney well aquifer includes sands and gravels that were
6 deposited as outwash or ice contact materials as the
7 glaciers receded from the area. However, in one area that
8 extends from about where the purge well is on the golf
9 course underneath Manticoke Creek and over to some point
10 underneath the sewage treatment plant, a large chunk of ice
11 broke off from the glaciers as it receded from the area.
12 And as that material melted, it created a pond
13 approximately 50 feet deep. With time, that pond sediment
14 accumulated at the bottom of the pond through natural
15 processes and flooding of the Susquehanna and the nearby
16 creeks and that kettle deposits filled with a fine grain
17 silt and sand material.

18 Now, this becomes important when we get into the
19 distribution of contaminants at the site because the sands
20 and gravels are very permeable and naturally flow back to
21 your ground water. However, the kettle deposit is a
22 barrier to ground water flow. It restricts ground water
23 flow and in many cases traps contaminants underneath the
24 kettle or forces them to go around the margin of the

END 002

1569

Endicott Wellfield hearing

10

1 kettle.

2 The surface deposits at the site are primarily
3 recent deposits associated with the flooding of the creeks,
4 fine sands, silts and clays. In the area of the sewage
5 treatment plant, there is approximately 20 feet, plus or
6 minus, of embankment fill materials that were used when
7 they constructed the plant to get it up out of the flood
8 plain.

9 Monitoring wells that we installed we measured
10 the ground water elevations on a regular basis to give us
11 an indication of the ground water flow, directions and
12 other conditions occurring in the ground water.

13 Now, regionally the ground water pattern is
14 typically from the north to south from the high-up lands
15 towards the Susquehanna River. But due to the pumping of
16 the Ranney well and the purge well to a lesser extent, this
17 regional north/south pattern is modified such that ground
18 waters flow generally from west to east at the site. You
19 can see as you approach the wells, there's a cone of
20 influence drawing water in towards the pumping well. In
21 fact, the computer modeling indicated that the Ranney well
22 has a very large zone of influence and it draws water in a
23 western direction as far as areas west of the Endicott
24 sewage treatment plant and the areas of the Tri-Cities

END 002

1570

Endicott Wellfield hearing

11

1 Airport, which is approximately a mile away from the Ranney
2 well.

3 The sampling at the site determined that there
4 were approximately 20 volatile organic chemicals found
5 either in the monitoring wells, sediment samples, leech-aid
6 outbreak samples, various sources that we tested. The
7 majority of these contaminants were found at levels greater
8 than ten parts per billion. Several of them were found at
9 one part per billion and they may have been found in an
10 isolated location. Of these contaminants, these were due
11 primarily to their most wide-spread occurrence at the site
12 and the most elevated concentrations and those include
13 vinyl chloride, chlorethane and trans-1,2-dichlorethene.

14 The distribution of contaminants is depicted on
15 this drawing. This generally shows the distribution of
16 vinyl chloride that we found in the ground water. For
17 reference, the Ranney well is down in this area.

18 Now, this shows that the most contaminated
19 material, contaminated ground water was found in our well
20 EW-3 deep where we found vinyl chloride in excess of 100
21 parts per billion and that was sampled, I believe, on three
22 or four occasions and it continued to be in excess of 100
23 parts per billion.

24 Beyond that, you have the green is less than 100

END 002

1571

Endicott Wellfield hearing

12

1 and greater than 50 parts per billion. The orange is 25 to
2 50 parts per billion and the yellow between 10 and 25 parts
3 per billion. This distribution of contaminants in the
4 ground water is indicative of what's called a slug flow
5 contaminant problem where a slug of contamination enters
6 the ground water, flows in the same direction as the ground
7 water and ultimately discharges at a discharge location.
8 In this case, it would either be Ranney or purge well.

9 Now, this is different from a continuous source
10 of contamination. If there was an ongoing source of
11 contamination, you'd find the highest source of
12 contamination at the contaminant source and then would
13 spread and decrease as it flowed with the ground water.

14 Our theory that we developed at this site is
15 that these contaminant slugs were introduced into the
16 Ranney well aquifer as a function of the flooding of the
17 Susquehanna River. We believe that the Susquehanna flood
18 inundated the landfill, in this case the Endicott landfill,
19 forced the ground water back into the catchment of the
20 Ranney well and with time, the contaminant was sucked down
21 by the Ranney well underneath the kettle deposits that I
22 showed you before and ultimately got its way into the
23 Ranney well.

24 Potential sources of contaminants that we have

END 002

15712

Endicott Wellfield hearing

13

1 identified in this study are shown on this map. The ones
2 in green were judged, for various reasons, to be less
3 likely sources of contamination for various reasons which
4 may include the distribution of contaminants that were
5 found via the down-grading of the wells were not
6 contaminated, the distance was too far or the ground water
7 flow directions were not suitable to the purposes we had.

8 But in any event, the Endicott landfill which is
9 immediately west of the sewage treatment plant and the
10 Town of Union landfill which is west of the Manticoke Creek
11 at this point appear to be the most likely sources of the
12 contamination that was encountered in the Ranney well and
13 it's our theory that the flooding is the mechanism that
14 drives the contamination out of these landfills and into
15 the catchment of the Ranney well.

16 Just briefly in summary, the results of this
17 study indicate, obviously, that the Ranney well is a major
18 source of ground water to the municipal system of Endicott,
19 that contamination was found in 1981 and it's been
20 confirmed by subsequent testing. Low level of volatiles
21 continue to reach the Ranney well and the source of the
22 contamination has not been found.

23 The site conditions that we determined include a
24 thick sand and gravel deposits that comprise the Ranney

END 002

1573

Endicott Wellfield hearing

14

1 well aquifer. The ground water flows from west to east
2 across the site in response to the pumping of the Ranney
3 and purge wells. The primary contaminants found in the
4 Ranney well continued to be volatile organics, particularly
5 vinyl chloride, trans-1,2-dichloroethylene and chloroethane,
6 and the distribution of these contaminants is indicative of
7 a slug flow rather than a continuous source of
8 contamination.

9 We believe the most likely source of these
10 contaminants include the Endicott landfill and/or the
11 Town of Union landfill.

12 Therefore, we are recommending that additional
13 studies be done to further evaluate these potential sources
14 of contamination. But in the interim, we believe that some
15 sort of symptomatic remediation must be done such that the
16 water is continuously below the current standards.

17 Ultimately, the goal should be to clean up the
18 source of the contamination. Now, to discuss this system
19 remediation, Mike O'Hara from TAMS is going to speak on the
20 feasibility study done.

21 MR. O'HARA: The purpose of the feasibility
22 study of this project is to determine what, if anything,
23 needs to be done based on the remedial investigation
24 description of the site and the problems. As the remedial

END 002

1574

Endicott Wellfield hearing

15

1 investigation was -- the conclusions were coming in from
2 that on-site conditions, we started thinking about what
3 would have to be done to start formulating alternatives and
4 approach to the feasibility study.

5 Based upon what Ray described on the remedial
6 investigation, we decided that the objectives for remedial
7 action, there should be an immediate objective and that is
8 to provide drinking water acceptable for long-term use in
9 the sense that occasionally low levels of volatile organic
10 contaminants were showing up in the area and so we want to
11 remediate at the Ranney well and that's our objective in
12 this study. And as Ray also mentioned, ultimately, when
13 the source of contamination is found we want to remove or
14 contain the source of contamination and also remediate
15 ground water that is contaminated that is between the
16 source and the Ranney well so that we provide the ultimate
17 protection for the drinking water.

18 In this feasibility study, just to give you a
19 brief rundown on what we do here, we start looking at all
20 the different technologies that are available to provide
21 this treatment at the well. We find the ones that appear
22 to be operable here and we provide different alternatives
23 for.

24 For our study, we developed seven alternatives;

END 002

1675

Endicott Wellfield hearing

16

1 six, but another one being a no-action alternative which
2 must be included in the analysis just as a business case.
3 Then we analyzed the alternatives for several different
4 factors; reliability, cost effectiveness, timeliness, how
5 quickly can it be implemented, does it take years or is it
6 something we can do right away.

7 After that kind of analysis, then we select
8 remedial action and we recommend a remedial action. The
9 recommended remedial action here is air stripping the
10 Ranney well to provide direct treatment and direct removal
11 of the volatile organic contaminants that show up
12 occasionally and continue to use the existing purge well
13 that has been operating for several years.

14 The system components here, the major one is the
15 air stripping, and this is broken down into several
16 different other components. The air stripping is a device
17 that is removing the volatile organic contaminants, but
18 there are other aspects of implementing that are required.
19 These are modifications to the system out at the Ranney
20 well. We need a valve manifold box so that we can direct
21 flow to each of the towers which I'll describe in a minute,
22 the stripping columns with blowers are required.

23 Basically what we have come up with in a
24 conceptual design is two air-stripping towers that would be

END 002

1576

Endicott Wellfield hearing

17

1 approximately 10 foot in diameter each by 16-feet high.
2 And each would contain 8 feet of packing material and the
3 counter-current flow of air and water through this tower
4 would provide the stripping of the volatile organic
5 chemicals. After that, after the stripping, we would have
6 to go to a clear well so that the water that has been
7 treated can be put back into the water distribution system
8 and so we also need new pumps for that.

9 And also, as a back-up system a new chlorination
10 system just in case the air stripper fouls, the plastic
11 media used in the air stripper becomes fouled. This is
12 really a back-up system. We don't know of any cases where
13 this has happened, but it's probably good to have this kind
14 of system as a backup in case the stripper gets fouled.

15 The other component is to keep the existing
16 purge well operating. And basically what we recommend here
17 is that a new well be installed at the same location at the
18 same depth and the same pumping rate and also that there's
19 flow measurement capability. That existing purge well
20 appears to be effective in reducing the contaminants, but
21 we want to make sure that it's operating correctly, that we
22 can measure the flow at all times.

23 Just another word about the selection of these
24 two items together. We really want to keep the existing

END 002

15777

Endicott Wellfield hearing

18

1 purge well going so that we have a good basis for design
2 for the air stripper. We have some new data over the last
3 few years on the levels of contamination reaching the
4 Ranney well with this purge well in operation and if we
5 stop the operation of the purge well, we felt that the
6 design basis for the stripper, in other words how much the
7 stripper would have to remove, becomes a little more
8 questionable and so, it appears to be more reliable to go
9 to the two-phase system.

10 Just quickly to describe what that air stripper
11 does; the water containing low levels of contaminants is
12 pumped into the top of this tower and this has plastic
13 packing material in most of the tower. Air is blown into
14 the tower so you have this counter-current flow and coming
15 out of the top of the tower are the volatile organic
16 compounds that are stripped out. And the treated water is
17 then put back in the distribution system and in this
18 diagram, it would be in this sump and then into the
19 distribution system.

20 And just a little sketch on the internals of the
21 tower, this shows what I just described, water coming in,
22 going through this medium, the air coming in, that the
23 counter-current flow, the air out with the contaminants
24 that have been stripped and the treated water back to the

END 002

157B

Endicott Wellfield hearing

19

1 distribution system for use.

2 As far as reliability, this technology was
3 piloted several years ago. The Village of Endicott and
4 New York State Fish and Water Resources worked with a
5 vendor to do some piloting with this and the contaminants
6 involved very easily stripped. And so in terms of
7 reliability, we felt that this was -- this approach, the
8 air stripping, was very reliable.

9 Just to show an approximate layout where this
10 would fit in down at the Ranney well, this is the existing
11 Ranney well and right now, without any treatment, the water
12 pumped out of the Ranney well goes right through the
13 distribution system. What we are recommending for this air
14 stripping is this valve manifold box where we can route the
15 flow either to the stripper or if the stripper is not
16 operating, through the distribution system, reroute it to
17 these two strippers. And as I said, these are towers
18 approximately 10 feet in diameter each by 16-feet high.
19 These would be on a concrete pad and enclosed in a small
20 building would be the blowers that would be used to supply
21 the air for stripping. This would be to protect the air
22 quality since this air is going for treatment of drinking
23 water. Then the treated water would go to this clear well,
24 you think of it as a reservoir and then be pumped back into

END 002

1679

Endicott Wellfield hearing

20

1 the distribution system and there would also be
2 chlorination after treatment.

3 Presently, the chlorination of the drinking
4 water is in the Ranney well. We would maintain that system
5 as the backup if we ever needed to clean the strippers, if
6 they ever became fouled. So that would be kept as a
7 backup, but a new chlorination system would be used for
8 routine chlorination.

9 So, this system can be fit in pretty well with
10 the existing Ranney well. We had mentioned something about
11 the record of decision. As far as the implementation of
12 this recommended remedial action, the record of decision is
13 expected to be signed in September, and then what happens
14 the efforts remaining before implementation are detailed
15 engineering design of this alternative. What we have done
16 in this study is a conceptual design. This is an
17 approximate layout, approximate sizes. What has to be done
18 next is detail design and this would nail down a lot of the
19 specifics of the design, and then construction after the
20 detail design. So, this is the approximate schedule, and
21 the spring of '89, when construction is ended, is when the
22 stripper would come on line and start to treat.

23 MS. MILLER: It would operate continuously?

24 MR. O'HARA: Yes. This stripper will operate

END 002

1580

Endicott Wellfield hearing

21

1 continuously. Also as part of this study, there were two
2 health risk assessment reports done; one was the existing
3 assessment of health risk, and then another one was done
4 after our recommended alternative was formulated to see
5 what kind of change that would effect in the health risk.
6 Basically, the roots of exposure in this situation would be
7 ingestion through drinking, inhalation and dermal
8 absorbtion through bathing. And based on the methodology
9 for performing these health risk assessments, total health
10 risk is 2 .5 times ten to the minus fifth. And 1 times 10
11 to the minus six is the health risk that's aimed for as an
12 acceptable health risk. So, the health risk existing now
13 is just slightly -- just slightly more than the desired
14 health risk.

15 When we went through the same methodology with
16 the stripper in operation, since the levels of toxic
17 materials would now be below detection limits, the expected
18 health risks would be -- is expected to be substantially
19 less than ten to the minus six. So, again in terms of
20 health risk, the air stripper and purge well is acceptable.
21 And I think that was it.

22 MS. MILLER: That's, in brief, a description of
23 the entire remedial investigation feasibility study. We
24 would anticipate that you may have questions with regard to

END 002

15871

Endicott Wellfield hearing

22

1 the presentations tonight or something you may have read in
2 the report. Bob Cozzy from our office in DEC will be
3 handling most of the questions and at this time, we will
4 open it up for questions from the audience. We would ask
5 you one thing, and that is that we are having this whole
6 meeting transcribed here, taken down, and so when you are
7 recognized to ask a question, would you please identify
8 yourself and speak at a volume that you can be heard.
9 Anyone who would like to ask questions at this time?

10 MR. MATERESE: Rick Materese, trustee in
11 Endicott. In the first presentation where you stated low
12 levels of contamination are still detected at times at the
13 Ranney well, now, is that greater than the four parts per
14 billion that the state allows or is that less than but
15 still is detected?

16 MR. KAMPFF: Generally it's less than the four
17 parts per billion in the case of vinyl chloride. There is,
18 in some instances, spikes of contamination detected in the
19 Ranney well, but it doesn't appear -- it's not a consistent
20 pattern. It shows up one week, but it is not a repeatable
21 value, so there's not a consistent contamination occurring
22 at the Ranney well.

23 MR. COZZY: You mentioned a level of four parts
24 per billion. The federal government limit is two parts per

END 002

15882

Endicott Wellfield hearing

23

1 billion and the state is in the process of adopting the
2 federal limits. For all intents and purposes, the state
3 limit is now two parts per billion.

4 MR. MATERESE: In 1984 was it four?

5 MR. COZZY: This was recently adopted in June.

6 MS. MILLER: Let's address then the spikes of
7 contamination and Dr. Gaffney, would you care to address
8 that?

9 DR. GAFFNEY: Well, the number in 1982 was five.
10 That's a guideline and that still, in a sense, exists on
11 the books. Now, that's a guideline; in other words,
12 something we operate to that. To say there's a health
13 problem if we exceed it but it doesn't exist as a standard
14 so tomorrow morning we are going to close down the place or
15 go to courts. You basically deal with that by explaining
16 to people that there is a risk and the exposure needs to be
17 eliminated. However, from the beginning we have always
18 discussed getting these numbers. It would be
19 non-detectable, because vinyl chloride does happen to be
20 the one carcinogen we are concerned about in water that we
21 know, proven, causes human cancers as opposed to many of
22 the other organic contaminants in water where we suspect
23 they cause human cancer based on the fact that they do
24 cause animal cancer but we don't have such direct human

END 002

1683

Endicott Wellfield hearing

24

1 exposure data.

2 MR. MATERESE: I understand that we would all
3 like to get that level down to a non-detectable level. I
4 guess my question deals with the fact that for the past
5 five years, then, or six years, I should say go back to
6 three years since we put in the purge well, have the levels
7 been at still a strong risk to the people, the 47 percent
8 of the village who gets that water?

9 DR. GAFFNEY: Well, as long as you're getting
10 detectable amounts occasionally, then we say that's a
11 health risk that can be eliminated.

12 MS. MILLER: But you're asking what are the
13 peaks that have occurred and have those peaks -- perhaps it
14 would be good at this time to explain what happens to the
15 Ranney well water as far as its incorporation into the
16 system and the testing of that water after it's
17 incorporated.

18 Gene, would you be able to address that
19 question?

20 MR. KUDGUS: Gene Kudgus, I'm public works
21 superintendant for the Village of Endicott. As was
22 mentioned, that well does supply about 47 percent of the
23 total production of water that we turn out. About half of
24 the amount of water that comes from the Ranney well does go

END 002

1584

Endicott Wellfield hearing

25

1 to local industry to be used as process water. The
2 remaining amount is distributed among the various tanks,
3 other distribution sites that we have so that when it does
4 get to the consumer, which is probably in the vicinity of
5 maybe 15 to 20 percent of the people in the entire system,
6 the levels have been non-detectable, because there is a
7 blending effect that occurs since the Ranney is not the
8 sole source of water but other sources of water are used to
9 provide that supply.

10 MS. MILLER: Does that help you?

11 MR. MATERESE: I guess that's the point I
12 wanted to get to.

13 MR. KUDGUS: So, even though we have had
14 occasional two parts per billion, three parts per billion
15 and then zero at the Ranney, as far as the consumer is
16 concerned, the consumer is getting none, non-detectable.

17 MR. MATERESE: I just wanted to make sure that
18 was stated. I didn't think that was. If no one else has
19 questions, I have a couple more.

20 MS. MILLER: Well, we will give you one more,
21 then we will give somebody else a chance.

22 MR. MATERESE: My second question dealt with
23 the air stripping and you said you want to have the two
24 things in case there's a malfunction. If the first -- if

END 002

1585

Endicott Wellfield hearing

26

1 the air stripper malfunctions and then it goes into the
2 chlorination system, you would never know that the air
3 stripper malfunctioned until the chlorinating system also
4 malfunctioned?

5 MR. O'HARA: No. The purpose of the two
6 systems is to provide a good design basis for the air
7 stripper so that we have a better design for the air
8 stripper. We don't have erratic peaks without the purge
9 well, so that's the reason to have the purge well. The air
10 stripper is very simple in operation and as long as the
11 blowers are operating, it is providing treatment and we
12 will know when the blowers are not working. And the down
13 time for that would be very, very minimal.

14 MS. MILLER: How would you know the blowers
15 aren't working?

16 MR. O'HARA: Well, it would be routine
17 inspection.

18 MS. MILLER: Gets quiet, you don't hear them
19 any longer. You would be able to detect.

20 MR. KUDGUS: We would also have that system
21 tied into alarms at our main water pump station in addition
22 to having a 24-hour water operator for the plant. So when
23 it was not working, we'd be aware of it immediately.

24 MS. MILLER: Does anyone else have a question?

END 002

15886

Endicott Wellfield hearing

27

1 MS. QUACKENBUSH: Deborah Quackenbush. I'm a
2 business owner here in Endicott. I have a couple of
3 questions. First, I'm curious about the pilot program that
4 you had mentioned how it was involved in similar type of
5 project or the design of this type, and I'm interested
6 where that was, how it's working and those types of --

7 MR. COZZY: I think what Mike referred to is a
8 pilot study that EPA had done and what they showed was that
9 typical air stripper removal efficiencies were 99 percent.
10 There are air strippers operating throughout the country,
11 one of which is in Brewster, New York, and they were
12 reported typical removals of 99 percent. That's the pilot
13 study I believe you're referring to.

14 MS. MILLER: Gene, you had some more
15 information?

16 MR. RUDGUS: We did a pilot study, Village of
17 Endicott did a pilot steady with Elaine Corporation
18 (phonetic) which is a vendor that produces studies of
19 facilities of this nature, and we took it upon ourselves to
20 call them in and pay for them to set up a portable
21 treatment facility to evaluate the effectiveness and the
22 potential of that mode of treatment for our water supply.
23 That was done several years ago. That report's available,
24 too.

END 002

1587

Endicott Wellfield hearing

28

1 MS. MILLER: Maybe this would be a good time to
2 have Bob just mention, we will get back on your second
3 question, Debbie, though, what it would have to meet as far
4 as air emission requirements.

5 MS. QUACKENBUSH: That was my next question,
6 about the air quality in. You mentioned quality checking
7 going in but you didn't mention it going out.

8 MS. MILLER: Let's address that right now. You
9 see, great minds --

10 MR. COZZY: Air stripper will have to meet the
11 New York State air guideline requirements. In addition,
12 there's a national emission standard for vinyl chloride of
13 ten parts per million. What we will actually see out of
14 this air stripper is in the order of ten parts per billion
15 which is less than one percent of what the standard is.
16 This amounts to less than five pounds of vinyl chloride per
17 year going to the atmosphere. The requirements set are New
18 York State alone.

19 MS. MILLER: But there are state requirements
20 that such a facility would have to meet and that would be
21 monitored for meeting those standards.

22 MR. COZZY: Right. There's also the federal
23 requirement for vinyl chloride which will be met.

24 MS. QUACKENBUSH: I do have a couple more.

END 002

15000

Endicott Wellfield hearing

29

1 MS. MILLER: Then we do have to give the other
2 gentleman a turn, too. Anyone else? We will go back to
3 you again.

4 MR. MATERESE: Going back to that same
5 question. Rick Materese, trustee. Going back to that same
6 idea, we will meet the standards, but will that affect,
7 even though it's in the atmosphere, will that affect the
8 ground directly around that pump station?

9 MR. COZZY: That was, as far as the
10 contaminants, that was also addressed in the health risk
11 assessment for the alternative and the bottom line is that
12 it's -- the risk due to cancer is much less than one times
13 ten to the minus six. In fact, it's less than one times
14 ten to the minus seven due to the air, the contaminated air
15 coming from the air stripper, so it would did he reduce the
16 risk from drinking the water.

17 MR. MATERESE: But what would be --

18 MS. MILLER: Are you saying would it go in the
19 air and contaminate the soil? That's what you're talking
20 about?

21 MR. MATERESE: Yes.

22 MS. MILLER: The impact from the air emissions
23 on the soil?

24 MR. COZZY: On the soil.

END 002

1589

Endicott Wellfield hearing

30

1 MS. MILLER: And if it's meeting the standards
2 in the air emissions.

3 MR. COZZY: Not really. It's a gas, it won't
4 disburse in the atmosphere. It won't settle to the ground.

5 MS. MILLER: It disburses then it meets the
6 standards for that ambient air and, therefore, the
7 standards, we are saying, wouldn't have an impact.

8 MR. COZZY: The standards are based such that it
9 wouldn't have an impact at ground level so many feet from
10 the stack itself.

11 MS. QUACKENBUSH: I will finish up with two
12 questions. Apparently it appears that we will have a
13 decision that this is basically what will have to be done
14 out there. The construction costs for this fix, will there
15 be some assistance for the Village of Endicott in this
16 area? And then the other question I have is the schedule
17 to monitor the water quality after the system is put in and
18 what will --

19 MS. MILLER: Let's have Bob describe what the
20 funding mechanism is for such a site and then Gene go over
21 what he plans to do for the testing.

22 MR. COZZY: The way the funding would work is
23 for the construction of the air stripper, the USEPA who's
24 funding the study would pay for 90 percent of the

END 002

11690

Endicott Wellfield hearing

31

1 construction costs and the state would pick up the other
2 ten percent. In addition to that, the first year's
3 operation and maintenance costs would be picked up
4 90 percent by EPA, ten percent by the state. After the
5 first year, the first year's considered start-up costs.
6 After the first year, the end users pick up the operation
7 and maintenance of the system.

8 MS. MILLER: But that end use does not include
9 the original installation construction costs.

10 MR. COZZY: Construction costs are covered by
11 EPA and the state and the 90/10 percent.

12 MS. MILLER: To follow then, then the long term
13 is by the users. Gene, why don't you mention your existing
14 monitoring program and then what you would plan.

15 MR. KUDGUS: Right now we are required to test
16 monthly, but again, we have taken it upon ourselves to
17 provide more data than is required, so we test now every
18 two weeks. In the future, I think, Kent, the requirement
19 will be monthly, as well.

20 KENT: Minimum of monthly.

21 MR. KUDGUS: And we will probably continue our
22 two-week testing. I will also probably be proposing to our
23 board that the water laboratory that we have now acquire
24 the necessary equipment so that we can perform those tests

END 002

16971

Enaticott Wellfield hearing

32

1 in-house at a considerable savings.

2 MS. MILLER: Any other questions?

3 MR. MATERESE: My last question, I think, you
4 stated that once the water goes through the blower system,
5 it will then go into another chlorination system and it's
6 already been chlorinated in the Ranney well. Is there any
7 danger of over chlorination to the water?

8 MR. O'HARA: No. The existing chlorination
9 system will not be used. It will be there, it will be
10 useable, but it will not be used. The only purpose in
11 keeping that is in case the stripper media gets fouled,
12 then that would be chlorinated itself, but the existing
13 chlorination system will not be used. The water's only
14 chlorinated once at the end.

15 MS. MILLER: Any further questions? No further
16 questions from the -- how about some of our reporters here?
17 Do you have any questions you want to ask? Any of the
18 panel have anything further they'd like to say?

19 MR. SCHOFIELD: Dan Schofield. You've got
20 \$147,000 a year operation cost.

21 MS. MILLER: Yes.

22 MR. SCHOFIELD: Is that what the anticipated
23 operation costs is going to be?

24 MR. COZZY: Yes. I believe that's on the

END 002

16912

Endicott Wellfield hearing

33

1 electrical usage for the air stripper, the pumps and the
2 blowers.

3 MR. SCHOFIELD: Gene, maybe you can answer
4 this, is that about right?

5 MR. KUDGUS: Yes. I talked with Bob about
6 getting a breakdown of those costs because a portion of it,
7 of course, is power, some is staffing, other related
8 operation and maintenance, plus the water testing, and I
9 think as we discussed, a good portion of that cost was the
10 water testing, which prompted me to consider our
11 acquisition of the equipment so that we could formally test
12 this in-house. I hope to have some numbers for you and the
13 board soon on that.

14 MS. MILLER: Any other questions? If not, we
15 will adjourn the meeting. If you have any questions that
16 you'd like to ask of the panelists informally, come on up
17 and if something occurs to you this evening or later on and
18 you want to write it down, I'll give you that address
19 again. Bob Cozzy, New York State Department of
20 Environmental Conservation, 50 Wolf Road, Albany, 12233.

21 Thank you for coming this evening.
